Potential procedure for performing a lipid emulsion infusion in the case of abnormal NK toxicity test

Lipid emulsions for parenteral nutrition are available in various types including Intralipid™, Lipofundin™ and Lipovenös™. These are not drugs, but parenteral nutrition preparations.

The preparations can be administered as an infusion via a peripheral needle; one option is to give a parallel infusion via a 3-way valve - as a precaution, a drop counter can be used in addition. A further option is to dilute a lipid emulsion such as Lipovenös™ (1 x 100 ml) with a litre of saline solution and administer as an infusion over a period of approximately 3 hours. While we have never experienced complications with this procedure, we recommend always performing these infusions under specialist supervision and support.

One infusion per week is usually adequate; more are only indicated where test results are extremely abnormal. The same applies to the total number of infusions, which is based on NK toxicity test results.
